

Things that happens when you don't know what you are talking about

Author : muammar

In Debian, if there exists a [bug](#) in a version of a package in SID (let's take as an example GRUB2 version 1.97+20091125-1), and it has a severity marked as Critical, then it won't touch testing until such a bug is fixed... It is as simple as that.

What happen when?:

- a) You are not sure which [Debian release](#) you are using.
- b) You are not sure how Debian handles bugs reported with severity: critical.
